COMMUNITY FAQS

General User & Community FAQs

A friendly guide for everyday users and builders — Inaya Network's DePIN infrastructure and custody protocol.

Document INAYA-FAQ-COMMUNITY-V3 · Classification Public · October 2026

SECTION Q1

What is Inaya Network in simple terms?

Think of it as a private, encrypted vault for your most sensitive files — identity documents, private keys, digital assets. Unlike Google Drive or Dropbox, which store your files whole on central servers, Inaya encrypts your data on your own device first, then splits it into pieces before anything ever leaves your browser. No single company — not even Inaya — ever holds a complete, readable copy of your file.

> No cryptographic system can honestly promise to be unbreakable — but this architecture is specifically designed so there's no single point where a complete, readable copy of your data ever exists outside your own control.

SECTION Q2

How does "file slicing" actually protect me?

It all happens inside your own browser before anything uploads. Your file is encrypted with AES-256-GCM, then split into two independent pieces — Shard Alpha and Shard Beta — cut at the exact binary midpoint. Each piece is stored independently. Either shard alone is meaningless, encrypted noise. Your file can only be reconstructed with your own private master passkey, which never leaves your device.

SECTION Q3

Do I need a monthly subscription?

No. Monthly/annual plans (Corporate Reserve) exist for large enterprise customers with predictable, high-volume needs. Everyday users pay Pay-As-You-Go — only for the exact amount of data actually stored, with zero commitment.

SECTION Q4

How much does it actually cost?

The current testnet rate, set on the deployed contracts, is 6.49 USDT per TB per month — about 0.0063 USDT per Gigabyte (GB) — plus a flat account fee of 12 USDT a year. Storage has no $INAYA fee at all. Downloading up to the amount you store is included every month; a $INAYA fee for retrieval beyond that is planned to activate at mainnet, not before. Rates are read live from the contract and may be adjusted by the protocol over time — always confirm the current rate in the app before uploading at scale.

SECTION Q5

What wallets are supported?

Inaya is built natively on BNB Chain. On the web app, any standard Web3 browser extension wallet (e.g. MetaMask) works. On mobile, wallet connection works via MetaMask Connect Multichain, connecting directly through a deeplink to the MetaMask app. There are no usernames or passwords for wallet-based features — your wallet is your identity.

> Business Workspace, Inaya Learn, and the public Security page don't require a wallet at all — email sign-in (or nothing, for public pages) is enough.

SECTION Q6

I'm a student / young developer — how can I get support?

The Inaya Foundation Scholarship & Grant Project is planned — equity-free micro-grants for young developers and cryptography students building with the Inaya Custody SDK, funded from the protocol's Ecosystem Fund allocation. It opens for applications after mainnet launch and is not yet accepting applications — follow official channels for the announcement.

SECTION Q7

What can I actually do with Inaya today, beyond storage?

- Inaya Learn — browse and watch curated educational videos on Web3, AI, and programming, with a built-in AI tutor. No wallet needed.
- Security — check whether a domain or IP has been flagged by the network's decentralized threat-intelligence layer, right from the public website. No wallet needed.
- Business Workspace — if your company needs document management with real approval workflows and permissions, it's a separate sign-up with just an email address.
- OS Home — once you're signed in (either with a wallet or a Business Workspace account), a single home screen now shows you what actually needs your attention: real notifications, a trust/health check on your data, and one search box that finds anything across every part of the app.
- Trust Center — visit inayanetwork.com/trust and independently verify Inaya's own security claims yourself, right in your browser, without logging in.
- Inaya Sign — sign a document with a real cryptographic signature tied to that exact document and moment, with an optional stamp onto the blockchain as extra proof.
- Node Operators — if you run an Inaya storage node, you now have your own dashboard for uptime, rewards, and network standing, separate from the wallet app.

SECTION Q8

What are Secure Chat, Secure Notes, Cleaner, and Meet?

Four new, optional additions to Business Workspace, each off by default until an organization turns it on. Secure Chat and Secure Notes are end-to-end encrypted — your organization's own server only ever sees scrambled ciphertext, never your messages or notes. Sharing got real upgrades too: links can expire, require a password, carry a watermark, or let an outsider upload a file to you securely. Inaya Cleaner is a desktop tool that finds junk and duplicate files on your own computer and never uploads a list of what it found anywhere — anything it removes goes to your recycle bin, never a permanent delete. Inaya Meet is a private video-calling feature where your camera and microphone connect directly between participants' devices rather than through an Inaya server.

> Honest limits worth knowing: the chat encryption library hasn't had an independent outside security audit yet. Meet's direct-connection design works best for smaller calls, not yet a large-meeting replacement. And underneath all of it, device keys now get an extra, future-proofing layer that combines today's encryption with a newer method designed to resist tomorrow's computers — on top of, not instead of, the encryption already protecting your data.
