

INSTITUTIONAL & ENTERPRISE FAQs

Institutional & Enterprise FAQs

Operational and compliance framework for institutional review of the Inaya Protocol.

Document INAYA-FAQ-INST-2026-V2 · Classification Confidential · August 2026

SECTION Q1

How is Inaya architecturally different from legacy decentralized storage?

Legacy decentralized storage protocols (Filecoin, Arweave) focus on commodity file hosting, where complete files often reside intact on a single node. Inaya operates as a zero-knowledge custody orchestration layer: files never leave the enterprise user's device in a unified state. Client-side encryption and binary sharding happen before anything reaches the network — the blockchain is used purely as an immutable metadata attestation log, never as file storage itself.

SECTION Q2

What is the current storage pricing model?

Pay-As-You-Go storage is billed in USDT, read live from the deployed contract's per-GB fee rate. As of this writing, storage ingress does not require a separate \$INAYA fee — \$INAYA's utility centers on staking, governance, and egress (retrieval), not the upload itself.

Correction from prior edition. An earlier version of this document stated a fixed "0.1 USDT + 0.1 INAYA per GB" dual-asset ingress model. That figure is stale and conflicts with the current live pricing structure. [VERIFY] the exact current per-GB rate with engineering before quoting a number in an institutional setting — it's read live from the contract and designed to move.

SECTION Q3

What are the enterprise storage tier options?

The real, implemented structure is the Corporate Reserve annual plan — a fixed data allocation billed once a year in USDT, with maintenance settled in \$INAYA-equivalent value.

ALLOCATION	RESERVE FEE (USDT/YR)	ANNUAL MAINTENANCE
250 TB / Year	13,500	500 USDT-eq.
500 TB / Year	27,000	1,000 USDT-eq.
1000 TB / Year	54,000	2,000 USDT-eq.

Correction from prior edition. An earlier version of this document described three API-request-volume subscription tiers ("Scale Matrix," "Established Swarm," "Institutional Node" at \$999–\$35,000/month). Those names and pricing do not exist anywhere in the codebase — confirmed against the custody-sdk's own corrected developer guide, which explicitly flags them as incorrect. The table above is what a corporate customer actually purchases today, verified against the live checkout flow.

SECTION Q4

How does client-side binary sharding work, mathematically?

On file ingestion, the browser runtime derives a key via PBKDF2 (100,000 iterations, HMAC-SHA256, 16-byte random salt), encrypts with AES-GCM-256, then splits the resulting ciphertext at its exact midpoint byte into two shards.

```
Mp = floor(length(C) / 2)
Shard Alpha = C[0 ... Mp-1]
Shard Beta  = C[Mp ... end]
```

Because neither shard contains a contiguous bit structure, an isolated compromise of any single storage node yields only random binary noise — external exfiltration from one node alone is not viable.

SECTION Q5

How does corporate revenue actually settle on-chain?

1. The customer approves USDT and calls `RevenueRouter.processCorporateInvoice()` — one on-chain transaction.
2. The client separately approves USDT and calls `InayaCorporateEscrow.createEscrow()` to escrow the node-operator's COGS share — a second, independent transaction.
3. The escrow releases that allocation over 12 fixed monthly payouts.

Correction from prior edition. An earlier version described this as a single atomic transaction with the router "automatically" invoking escrow creation. The deployed checkout flow is two separate, client-initiated transactions. [VERIFY] the specific revenue-split percentages (node/treasury/team) with the founders before restating them publicly — `RevenueRouter`'s Solidity source isn't tracked in this repository, only its deployed address, so this document can't independently confirm the split from code.

SECTION Q6

What does the unit-economics / margin structure look like?

[VERIFY] Specific gross-margin and EBITDA figures before quoting them to an institutional counterparty — prior materials have stated figures in the 50–61% gross margin and ~50% EBITDA range, but this document doesn't have a source of truth to reconcile those numbers against. Get one figure agreed with the founders and cite it consistently across every investor-facing document rather than each one stating a slightly different number.

SECTION Q7

Does Inaya offer anything beyond the storage protocol for enterprise buyers?

Yes — Business Workspace is a fully independent B2B SaaS product built on the same infrastructure: organizations, departments, projects, documents, server-enforced approval workflows, granular permissions, secure external sharing, and a permission-aware AI assistant. It's priced and evaluated like any other business software — an institutional buyer never has to engage with the token economics above to use it.
